Adherence to the guideline ‘Triage in emergency departments’: a survey of Dutch emergency departments

Maaike AP Janssen, Theo van Achterberg, Marian JM Adriaansen, Caroline S Kampshoff and Joke Mintjes-de Groot

Aims and objectives. The aim of this study was to evaluate the adherence to the 2004 guideline Triage in emergency departments three years after dissemination in Dutch emergency departments.

Background. In 2004, a Dutch guideline Triage in emergency departments was developed. Triage is the first step performed by nurses when a patient arrives at an emergency department. It includes the prioritisation of patients to ensure that doctors see patients with the highest medical needs first. Although the national guideline was developed and disseminated in 2004, three years on there was no insight into the level of implementation of the guideline in practice.

Design. A cross-sectional descriptive design.

Methods. In February 2007, data were collected from ward managers and triage nurses at all emergency departments in the Netherlands (n = 108), using a questionnaire that was based on the recommendations and performance indicators of the guideline.

Results. In total, 79% of all 108 Dutch emergency departments responded. The main findings showed that over 31% of the emergency departments did not use a triage system. Emergency departments using the Manchester Triage System had a mean adherence rate of 61% of the guideline’s recommendations and emergency departments using the Emergency System Index adhered to a mean of 65%.

Conclusion. The guideline Triage in emergency departments was disseminated in 2004, but results from this study indicate that an improvement in adherence to this guideline is required.

Relevance to clinical practice. Adherence to guidelines is important to standardise practice to ensure that patients receive the appropriate treatment and to improve quality of care.

Key words: clinical guidelines, compliance, emergency departments, implementation, nurses, nursing, triage

Adherence to the guideline triage

Background

Triage is the first activity performed by nurses when a patient arrives at an emergency department (ED). Triage is a process of decision-making to prioritise treatment and needs of patients in ED based on clinical urgency. Triage acuity is defined as classification of patient acuity that characterises the degree to which the patient’s condition is life-threatening and whether immediate treatment is needed to alleviate symptoms (Gilboy et al. 2005). Triage nurses classify patients on the basis of their need for medical attention: patients with the highest medical needs will be treated first (Manos et al. 2002, Eitel et al. 2003, Worster et al. 2004).

The number of patients arriving at EDs has increased over the past few years, partly because of self-referrals, resulting in overcrowded EDs. Therefore, there is a need for a system that prioritises patients in the order of urgency (Van Gerven et al. 2001, Roukema et al. 2006, Van der Wulp et al. 2008). Worldwide, different triage systems are used. Systems most commonly used are the Australasian Triage Scale (ATS, Australia, New Zealand, Hong Kong and Belgium), the Canadian Emergency Department Triage and Acuity Scale (CTAS, Canada), the Emergency Severity Index, also known as the Boston System (ESI, United States) and the Manchester Triage System (MTS, United Kingdom) (Cronin 2003, Murray et al. 2004, McCallum Pardey 2006, Gerdtz & Bucknall 2007, Van Veen & Moll 2009). All these different triage systems include assessment of the patient’s most important complaint, combined with a physical examination, leading to an urgency rating. This rating indicates the length of time a patient can wait safely before being seen by a doctor (Gerdtz & Bucknall 2000).

Although the need for a system for urgency classification of critical care patients was known, Dutch EDs did not use standardised triage systems prior to 2004. There was no protocol or guideline for urgency rating. Patients were seen by medical staff in the order of arrival instead of urgency of care, which could lead to serious consequences. This undesirable situation required changing.

Therefore, the Dutch Institute for Healthcare Improvement (CBO) and the Dutch Society of Emergency and Accident Nurses (NVSHV) developed a guideline for systematic triage in EDs in 2004 (NVSHV 2004, Elshove-Bolk et al. 2007). The 2004 guideline Triage in emergency departments provides direction regarding implementation, training, resources, performance and evaluation, for nurses working in EDs in determining the urgency of patients. The guideline further offers ward managers at the EDs guidance in policy making (Bergeron et al. 2004, Göransson et al. 2005).

The introduction of the guideline in 2004 was no guarantee that the guideline would be used in practice. Research on the implementation of guidelines indicates that the use of guidelines is not always reflected in the care patients receive in practice (Meijers et al. 2006, Francke et al. 2008, Kitson et al. 2008, Forsner et al. 2010). This is also referred to as the gap between theory and practice. As a consequence, patients often do not receive the care they need (Estabrooks 1998).

This study provides insight into the current practice of triage in Dutch EDs and the level of adherence to the guideline. For this study, we formulated the following research question: what is the degree of implementation of the 2004 guideline Triage in emergency departments in Dutch EDs three years after its dissemination? Furthermore, the findings of this study and new available research findings on triage will be used to update the guideline and guide implementation activities.

Methods

Study design and setting

A cross-sectional descriptive design was used. A questionnaire was developed based on recommendations and performance indicators of the 2004 guideline Triage in emergency departments. Questions were formulated on all recommendations and performance indicators of the guideline. To ensure content validity, the questionnaire was evaluated by two members of the NVSHV, two Health Care workers at the EDs (ward manager and registered nurse), two persons of the Netherlands Centre for Excellence in Nursing (LEVV) and one person of the Scientific Institute for Quality of Healthcare. They critically reviewed the questionnaire on content and clarity of answering scales and on completeness of all aspects of triage.

For this study, a full population sample was used, including ward managers of all EDs in the Netherlands (n = 108). The ward managers were asked to distribute the questionnaires to one registered ED nurse trained in triage (triage nurse). Ethical approval was not needed as the questionnaire did not ask participants for medical or highly personal information and did not require a large amount of time to complete (http://www.cccmo-online.nl/main.asp?pid=1&taal=1).

Measures

The questionnaire was divided into two components: the first component had to be filled in by a ward manager and the second by a triage nurse working in the ED. The first part of the components was identical and was related to the type of organisation, dissemination (acquaintance with the guideline)
and use of triage systems. Only EDs using a triage system were asked to answer the follow-up questions related to adherence to recommendations from the guideline (process of triage, competences of nurses and implementation of triage). Ward managers received extra questions related to the approach of implementation and performance indicators of the guideline (process, structure and outcome measurements). For the performance indicators, evidence from clinical information was requested (Appendix).

Answering scales were a two-point scale (‘yes–no’) or a six-point scale (‘always–mostly–often–regularly–sometimes–never’). In the introduction mail, a clarification was given for the six-point scale: ‘always’ meant if all nurses/doctors performed the activities all the time (100%), ‘mostly’ meant within 80–99%, ‘often’ within 60–79%, ‘regularly’ within 40–59%, ‘sometimes’ within 1–39% and ‘never’ 0%. The questions included room for clarification.

Data collection

A list of hospitals in the Netherlands with the names of all EDs was collected from the NVSHV. All hospitals were contacted and asked whether the hospital had an ED and what the name of the ward manager was to whom we could send the questionnaire. Based on website information, university and teaching hospitals (http://www.rivm.nl, http://www.stz-ziekenhuizen.nl) were identified. The remaining hospitals of the list were classified as non-teaching hospitals. In February 2007, the questionnaires were sent to ward managers of all EDs (eight university hospitals, 28 teaching hospitals and 72 non-teaching hospitals) with the kind request to fill in the first part of the questionnaire and to distribute the other part to a nurse working at the department. Ward managers of triage-performing EDs, were asked to forward the questionnaire to a triage nurse, as nurses who perform triage and facilitate organisational aspects like education and rooming facilities. Nurses are responsible for the professional performance of triage. As university hospitals consisted of only eight hospitals, analyses of the university hospitals were grouped with analyses of the teaching hospitals.

Pearson’s chi-square tests were used to detect differences between groups (type of hospital and ward managers vs. nurses). To ensure the overall change of making a type I error for multiple comparisons, statistical significance was set at \( p < 0.0019 \) after Bonferroni correction (0.05/26 = 0.0019).

Results

A total of 158 of 216 questionnaires (73%) were returned (80 ward managers and 78 triage nurses). A total of 81 of 108 EDs (75%) returned the questionnaires. In addition, four ward managers responded by telephone, stating that they would not return the questionnaire, because their ED was already involved in other research concerning triage or was not using a triage system or implemented the guideline recently.

Type of organisation

The participating EDs were representative of the Dutch context. All eight university hospitals responded (100%).
For the 28 teaching hospitals, the response rate was 82\% (n = 23), and for the 72 non-teaching hospitals, the response rate was 69\% (n = 50).

**Dissemination**

All in all, 99\% of the ward managers (n = 79) and 92\% of the triage nurses (n = 72) knew about the national guideline. The main source of dissemination of the guideline was the Dutch Society of Emergency and Accident Nurses (NVSHV). Triage nurses stated that ward managers were also an important source. Table 1 shows other sources that were employed for the dissemination of the guideline.

**Triage systems**

Almost 39\% (n = 33) of the EDs did not use a triage system. Patients were seen by a nurse in the order of arrival instead of urgency of care. Two standardised triage systems were used at EDs in the Netherlands: 42 EDs used the MTS and six EDs the Emergency System Index (ESI). Four EDs reported the use of a self-developed triage system.

**Adherence to recommendations and performance indicators**

Figure 1 shows the adherence to all recommendations and performance indicators of the 2004 guideline *Triage in emergency departments* for each of the triage systems, based on the questionnaire of the ward managers. EDs that used the MTS had a mean adherence rate of 61\%, EDs using the ESI had a mean adherence rate of 65\%, whereas EDs using a self-developed triage system had a mean adherence rate of 29\%.

**Figure 1** Adherence to recommendations vs. type of triage system (%).

**Guideline implementation**

The questionnaire for the ward manager included questions related to the approach to guideline implementation. The answers to these questions are presented in Table 2. Some ward managers pointed out that the doctors were informed about the procedure of triage after triage was established. In 87\% of the EDs (n = 69), implementation of the triage system occurred by change agents consisting of a ward manager, a project leader or an advisor. About half of the EDs used a systematic method for implementation and reserved some type of budget for the implementation of a triage system.

**Training**

The guideline recommends that nurses performing triage follow an education in Acute Care, the Trauma Nursing Core Course (TNCC), the Emergency Nursing Paediatric Course (ENPC) and didactic training in triage. Furthermore, they

have to have more than one-year clinical work experience. On average, nurses had a more positive score on trained triage nurses compared with ward managers, except for training by colleagues. There were statistically significant differences in answers found between nurses and ward managers regarding TNCC and work experience (Table 3).

Resources
Table 3 shows the triage resources that were available in the EDs. Almost 80% of all EDs have created a triage room, whereas about 70% used an Information Communication Technology system (ICT system), formulated a triage workgroup and had information brochures in the waiting room.

Performance
Triage nurses did not always carry out triage of every patient arriving at an ED. According to the ward managers, a triage nurse saw nearly two out of three patients within five minutes of arrival. Pain assessment was carried out among almost all patients. Two out of every three EDs formulated a triage protocol based on the guideline for triage and consensus at the ED. The protocols contained agreements concerning the tasks of the triage nurse, what to do when the ED is crowded and the coordination of the patient flow.

Evaluation
Table 4 additionally presents results related to the evaluation of triage at the EDs. Over 50% of EDs evaluated the trial period. The evaluations led to changes related to responsibilities of the triage nurses and the doctors, interventions triage nurses are permitted to perform, content of triage assessments, development of pain protocols, ICT systems and use of triage rooms. Multidisciplinary reflection occurred less often than monodisciplinary reflection. Based on these evaluations, improvements were made associated with adding necessary supplies to triage rooms (e.g. computers, stretchers, thermometers, dressings), increasing personnel numbers (having triage nurses on day, evening and night shifts), agreements on the tasks of triage nurses, development of pain protocols and adjustments to ICT systems.

Discussion
This study was designed to examine the adherence of EDs in the Netherlands to the 2004 guideline Triage in emergency departments. Although the study is performed in a Dutch setting, the results may be relevant for other countries as well, indicating potential lack of adherence to triage guidelines in EDs.

The guideline was disseminated in 2004, and because most ward managers and nurses know about its existence, the

expectation was that nearly all EDs would use a triage system by now. Additionally, the Netherlands Health Care Inspectorate (IGZ) and the NVSHV recommend the use of the guideline, which should have advanced its use as well (NVSHV 2004, Jochems 2006). Nevertheless, over 38% of the EDs that filled in the questionnaire did not perform triage using a standardised triage system. Some EDs stated that they would implement a triage system within one year. Another reason why EDs have not implemented a triage system could be the fact that a new triage system is currently being developed: the Dutch Triage System (NTS). Collaboration between the Dutch College of General Practitioners (NHG), the NVSHV, the Netherlands Mental Health Care Association (GGZ Nederland) and the National Institute for Guidelines EMS (Stichting LAMP) should result in one system for telephonic and physical triage for all acute care settings (general practitioner, ambulance, ED and mental health care) (NTS 2006). An agreement has been made between the four

ICT system, Information Communication Technology system.
organisations that as soon as this new system is in place the acute care settings in the Netherlands must use this system. However, this process could take several more years and EDs need to perform systematic triage during this time.

The MTS is the triage system used most frequently. This could be explained by the fact that the guideline explicitly recommends this triage system on the basis of conclusions on triage in an earlier literature review (NVSHV 2004, Elshove-Bolk et al. 2007). The ESI is also used in the Netherlands. The use of other international triage systems was not found. Although the MTS and ESI are valid and reliable systems (Travers et al. 2002, Speake et al. 2003, Baumann & Strout 2007, Storm-Versloot et al. 2009), little research has been conducted on the validation of MTS and ESI for the Dutch context. One study assessed the reliability and validity of the MTS in two EDs in the Netherlands. The authors found a moderate to substantial inter-rater reliability, and nurses were consistent in their decision-making around urgency classification. The MTS appeared to be more sensitive in its use for children who need immediate or urgent care than for other patients in the ED (Van der Wulp et al. 2008). Two studies examined the validity of the MTS in paediatric emergency care. The authors found a moderate validity (Roukema et al. 2006, Van Veen et al. 2008). A fourth study looked at the validation of the ESI triage algorithm in self-referred patients in one ED in the Netherlands. The authors declared that the ESI triage algorithm is likely to be reliable in predicting the severity of patients’ condition in the Netherlands (Elshove-Bolk et al. 2007). Although these studies are available, more research into the validation and comparison of the two systems for Dutch EDs is needed. Four EDs used a self-developed triage system. It remained unclear how these self-developed systems functioned. These systems are not validated, and it appears that they have little in common with the recommendations of the guideline.

Guidelines are valuable tools to promote evidence-based practice. Although the dissemination of the guideline seems to be good, thorough implementation of the guideline seems to be lacking. Our study provides no clear insight into the factors that may have contributed to the moderate implementation of the guideline. One explanation could be that many EDs did not use a systematic approach to implementation (Grol & Wensing 2005). Another reason could be that only half of the EDs had a budget for the implementation of the guideline at their disposal. It is important that managers take into account that successful implementation of guidelines can lead to extra costs (Ploeg et al. 2007). Over 80% of the EDs made use of a change agent. Other studies suggest that the use of change agents facilitate guideline implementation (Doumit et al. 2007, Ploeg et al. 2007). Further research related to factors that influenced implementation of the guideline is needed to develop strategies to increase the use of the guideline.

Evaluation is an important step in the process of implementing a guideline (Grol 1997, Wollersheim et al. 2005). Performance indicators can be used to evaluate the use of the guideline (Wollersheim et al. 2005, Forsner et al. 2008). The indicators give insight into the delivered quality of patient care. Furthermore, the actual care can be compared with the recommended care in the guideline (Nelen et al. 2007). Although ward managers can use the performance indicators of the guideline for policy making regarding triage, only half of the ward managers stated that they actually used the performance indicators. One reason for not using the indicators was that EDs did not have a digital registration system. Lack of resources to register indicators is one of the most important factors that hinders the use of performance indicators (Cabana et al. 1999, De Vos et al. 2010).

ED, emergency department.

An immense variance between the adherences to different recommendations of the guideline exists. The recommendation with the lowest rate of compliance is the ENPC. The highest rate of compliance was found for pain assessment. A study on clinical guidelines indicated different reasons for low compliance with recommendations. First, the recommendation could be incorrect because of a lack of scientific evidence for the recommendation. Second, the influence of the development group or the influence of different parties involved in development of the recommendation (for example, patients, doctors, managers and the government) (Woolf et al. 1999).

Some EDs modified a few recommendations. One recommendation often modified was ‘seeing patients within five minutes of arrival’, which was often changed to ‘within 10 minutes of arrival’ as five minutes was found to be too short. Rogers (1995) refers to this as re-invention of the innovation. Although this study gives insight into whether the recommendations of the guideline are used by the EDs, it provides no insight into the factors that influence the use of the guideline. Therefore, we recommend a study on factors that promote or hinder the uptake of the guideline.

Triage nurses and ward managers achieved overall similar scores in regard to the recommendations. Only statistically significant differences between the scores of triage nurses and ward managers were found among recommendations related to TNCC, work experience and measurement of patient satisfaction. Triage nurses had a higher score related to training and performance, while ward managers scored higher on the recommendations of evaluation. One explanation might be that the task of the ward managers is more focused on evaluation, whereas nurses are responsible for the performance of triage. No statistically significant differences were found between types of hospital.

Limitations

This study has some limitations that weaken the credibility of the findings. The first limitation is related to the development of the questionnaire. As the questionnaire was meant to gain insight into the adherence of the guideline, the questionnaire was based on all recommendations and indicators of the guideline. The questionnaire was only validated on content and clarity by experts, but no test-retest of the questionnaire was performed.

Second, as a self-reporting questionnaire was used, there is a possibility of an over- or under-estimation of compliance with the guideline as socially desirable answers may have been given. Third, the ward managers of each ED were asked to distribute the questionnaires to a triage nurse. This might have led to selection bias, as nurses could be chosen who already showed an interest in triage. They may have completed the questionnaire differently compared with other nurses at the department who do not agree with the department’s policy concerning triage. Despite the possible bias, we feel this study gives a balanced overview of what the level of adherence to the guideline is.

A fourth limitation is related to the response of EDs and type of hospital. Although the all-response rate was relatively high (75% of all EDs in the Netherlands), a difference in response rates was found between university, teaching and non-teaching hospitals. The university and teaching hospitals had a response of higher than 80%, whereas nearly 70% of the non-teaching hospitals responded. Although this could have biased the results from the non-teaching hospitals, we feel that the answers of the non-teaching hospitals represent were well represented, as 50 EDs participated. Furthermore, we found only one significant difference between university/teaching and non-teaching hospitals (registration of reason for not achieving target time).

Conclusions

In conclusion, dissemination of the 2004 guideline Triage in emergency departments appears to be good. Important sources of dissemination are the profession (NVSHV) and the ward managers. However, improvement is still required concerning the actual implementation of the guideline Triage in emergency departments. Further research into recent developments related to triage should be part of the updating process and dissemination of the guideline.

Relevance to clinical practice

Adherence to guidelines is important to reduce variations in practice and to ensure that patients receive the appropriate treatment and to improve quality of care. The results shown in this study suggest that the existence of a guideline does not mean that it is automatically transferred into daily practice. It also shows the need of further awareness for the use of performance indicators related to triage. More research on barriers that hinder the use of triage and strategies to implement triage in EDs is wanted. These research findings should support the revision and implementation of guidelines in EDs.

Acknowledgement

This study was funded by an unrestricted educational grant from the Foundation Innovation Alliance (SIA – Stichting...
Innovatie Alliantie) with funding from the ministry of Education, Culture and Science (OCW).

### Implementation of triage

18. Top-down implementation  
19. Multidisciplinary implementation  
20. Communication in terms of policy and instructions; consultation; information services; measurement and evaluation moments; feedback on (temporary) results  
21. Involvement of a change agent  
22. A triage room is available; how is this facilitated (second exit; alarm button; presence of camera, disinfectants, examination gloves, hand basin, other facilitations)  
23. Training in triage: (1) multidisciplinary, (2) time between training and implementation, (3) all new employees receive the training, if yes how, (4) trail to get acquaintance in triage (how long, evaluation after the trail, adjustments after trail)  
24. Reflection moments related to the triage process in multidisciplinary team  
25. Reflection moments related to triage process in monodisciplinary team  
26. A triage group is formulated  
27. Information Communication Technology system (ICT) is present  
28. Budget reserved for costs related to the implementation of triage (ICT, formation, training, information brochure, renovation costs for waiting room, other)  

### Quality indicators

(only filled in by ward managers)

29. Triage is imbedded in quality system  
30. Use of quality indicators of the guideline  
31. Registration of origin patient  
32. Registration of urgency codes  
33. Registration of moment of arrival at the ED until first contact nurse  
34. Registration of triage time (moment contact patients with nurse)  
35. Registration target time (first contact patients with doctors); conform the guideline  
36. Registration reason not meeting the target time  
37. Registration time patients leaving the ED  
38. Registration outflow reasons  
39. Registration reason retriaged patients  
40. Evaluation of patient experience (information on waiting times and urgency codes, pain, privacy and treatment)  
41. Evaluation of experiences personnel (aggression, triage system, ICT system, triage room)  
42. Registration of aggression per month/year at the ED (before/after triage)  
43. Decrease in waiting times after implementation of triage  
44. Decrease in completion time after implementation of triage

If questions were filled in with ‘no’, reasons why not were asked.
